Aster Vale Demonstration Clinic (fictional)

Respiratory consultation

Patient: Daniel M. (synthetic) | ID: SYN-001 | DOB: 1978-10-06

Encounter: ENC-001-07 | Source: DOC-001-07 | Type: specialist_note

Clinical time: 2026-07-22T09:40:00+03:00

Documented: 2026-07-22T12:45:00+03:00 | Author: Dr Ivo Fern (fictional)

SYNTHETIC — NOT FOR CLINICAL USE

History: Persistent cough and reduced exercise tolerance. Patient reports stopping lisinopril on July 8 and taking losartan thereafter. Cough has not clearly changed over the subsequent two weeks. Reflux symptoms improved with treatment. No hemoptysis.

Exam: BP 132/84 mmHg, saturation 96% on air, weight 77.2 kg; persistent right basal crackles.

Assessment: Etiology remains unresolved. Focal radiographic opacity and inflammatory-marker trend need further characterization. A short interval after stopping an ACE inhibitor does not settle its contribution. Anxiety may coexist and does not explain the imaging finding by itself.

Plan: CT chest booked for July 29; no completed CT result is available in this record. Spirometry requested; no result yet. Review after imaging; urgent return for worsening breathlessness, chest pain or hemoptysis.
